

Probability Theory & Mathematical Statistics

Continuous Random Variable

Continuous Random Variable

Random Variable

- Given $(\Omega, \Sigma, \text{Pr})$, a random variable is a function $X : \Omega \rightarrow \mathbb{R}$
 - satisfying that $\forall x \in \mathbb{R}, \{\omega \in \Omega \mid X(\omega) \leq x\} \in \Sigma$ (i.e. X is Σ -measurable)
- Events: $X \in B$, where $B \subseteq \mathbb{R}$ is countable \cap, \cup, \setminus of intervals $(a, b]$
- The cumulative distribution function (CDF) (累积分布函数) of a random variable X is the $F_X : \mathbb{R} \rightarrow [0, 1]$ given by

$$F_X(x) = \text{Pr}(X \leq x)$$

- CDF $F_X : \mathbb{R} \rightarrow [0, 1]$ is monotonically nondecreasing with

$$\lim_{x \rightarrow -\infty} F_X(x) = 0 \quad \text{and} \quad \lim_{x \rightarrow \infty} F_X(x) = 1$$

Continuous Random Variable

- A random variable $X : \Omega \rightarrow \mathbb{R}$ is called continuous, if its CDF can be expressed as

$$F_X(x) = \Pr(X \leq x) = \int_{-\infty}^x f(u) \, du$$

for some integrable function $f : \mathbb{R} \rightarrow [0, \infty)$

- f is called probability density function (pdf) (概率密度函数) of X .

Probability Density Function

- The density function f is *NOT* uniquely determined by $F_X(x) = \int_{-\infty}^x f(u) du$
 - If F_X is differentiable then we normally set $f_X(x) = F'_X(x)$
 - For continuous random variable X , it holds that

$$\Pr(X = x) = 0 \text{ for all } x \in \mathbb{R}$$

- The density value $f_X(x) \geq 0$ is *NOT* a probability, but a proportion (“*density*”)

$$\Pr(x < X \leq x + \Delta x) = F_X(x + \Delta x) - F_X(x) \approx f_X(x)\Delta x$$

Probability Density Function

- f_X is the density function of a continuous random variable $X : \Omega \rightarrow \mathbb{R}$, iff

- $\int_{-\infty}^{\infty} f_X(x) dx = \Pr(-\infty < X < \infty) = 1$

- $f_X(x) \geq 0$ for all $x \in \mathbb{R}$

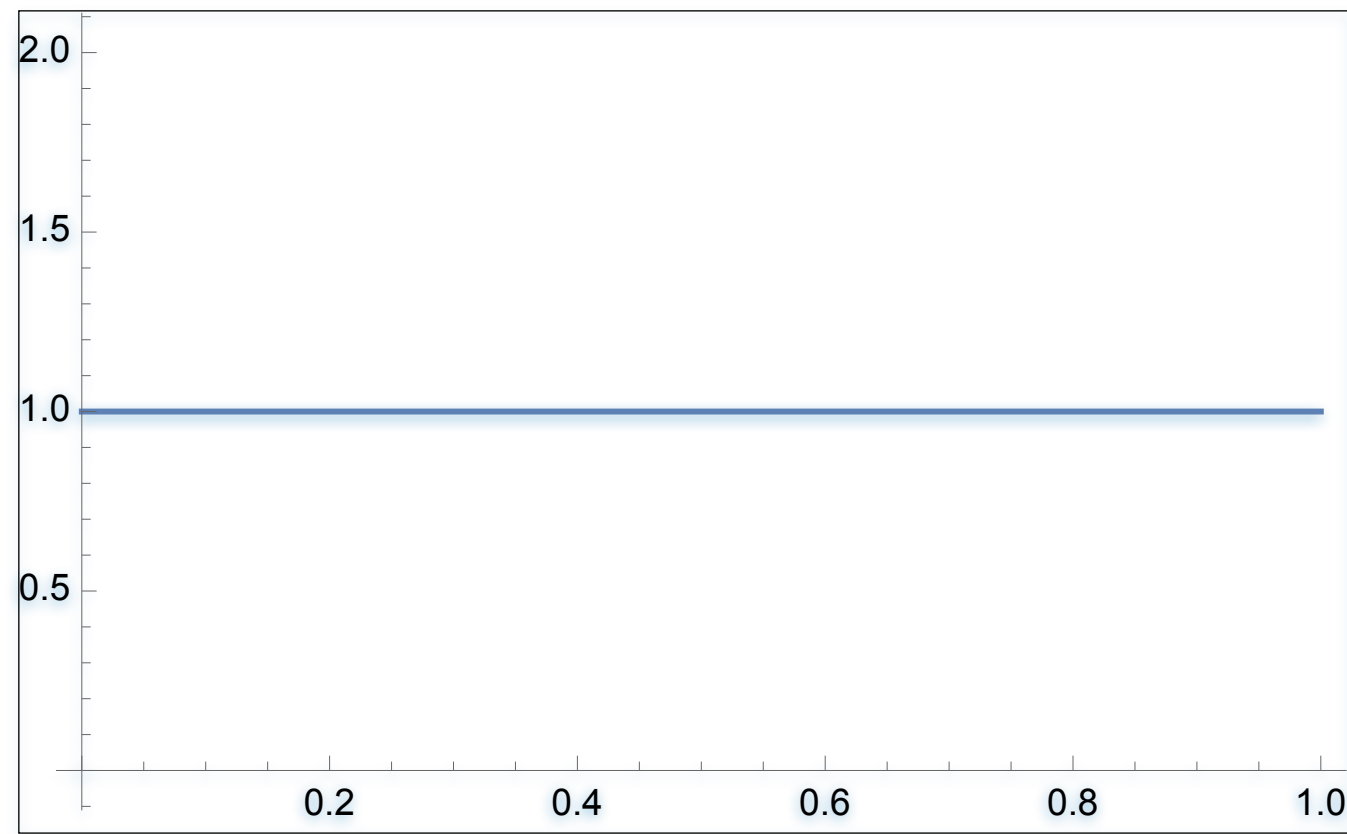

\implies

- $\Pr(a \leq X \leq b) = \Pr(a \leq X < b) = \Pr(a < X \leq b) = \Pr(a < X < b) = \int_a^b f_X(x) dx$

- $\Pr(X = x) = 0$ for all $x \in \mathbb{R}$

Examples

$$f_X(x) = I_{[0,1]}(x)$$

$$f_Y(y) = 6y(1 - y)I_{[0,1]}(y)$$

$$f_Z(z) = \frac{1}{\pi\sqrt{z(1-z)}}I_{[0,1]}(z)$$

CDF $F_X(x)$

CDF $F_Y(y)$

CDF $F_Z(z)$

Continuous Probability Space*

- Let \mathcal{I} be the collection of all open intervals in \mathbb{R} .

The Borel σ -field \mathcal{B} is the smallest σ -algebra that contains \mathcal{I} .

- Each $B \in \mathcal{B}$, called a Borel set, is a countable \cap, \cup, \setminus of open intervals.
- For Borel set $B \in \mathcal{B}$, the Lebesgue integral:

$$\mu(B) := \Pr(X \in B) = \int_B f_X(x) dx = \int_{-\infty}^{\infty} I_B(x) dF_X(x)$$

- $(\mathbb{R}, \mathcal{B}, \mu)$ is a well-defined probability space.
- If $g : \mathbb{R} \rightarrow \mathbb{R}$ is Borel-measurable ($\forall y \in \mathbb{R}, \{x \in \mathbb{R} \mid g(x) \leq y\} \in \mathcal{B}$), then $g(X)$ is also a random variable

Lebesgue Integration*

- Let $(\mathbb{R}, \mathcal{B}, \mu)$ be a probability (or measure) space.
- Assume that f is (Borel-)measurable and nonnegative. For $B \in \mathcal{B}$, define:

$$f^*(t) := \mu(\{x \in B \mid f(x) > t\})$$

- The Lebesgue integral is defined by:

$$\int_B f d\mu := \int_0^\infty f^*(t) dt$$

- For general f , let $f = f^+ - f^-$ for nonnegative f^+, f^-

VS

Joint Distribution

- The joint distribution function of X and Y is the function $F_{X,Y} : \mathbb{R} \rightarrow [0,1]$ given by

$$F_{X,Y}(x, y) = \Pr(X \leq x \cap Y \leq y)$$

- The random variables X and Y are (jointly) continuous with joint (probability) density function $f_{X,Y} : \mathbb{R}^2 \rightarrow [0, \infty)$ if for all $x, y \in \mathbb{R}$

$$F_{X,Y}(x, y) = \int_{v=-\infty}^y \int_{u=-\infty}^x f_{X,Y}(u, v) du dv$$

- $f_{X,Y}(x, y) = \frac{\partial^2}{\partial x \partial y} F_{X,Y}(x, y)$ (assuming $F_{X,Y}$ being sufficiently differentiable)

Marginal Distribution

- The marginal distribution functions of X and Y are:

$$F_X(x) = \Pr(X \leq x) = F_{X,Y}(x, \infty) = \int_{-\infty}^x \int_{-\infty}^{\infty} f_{u,Y}(u, y) \, dy, \, du$$

$$F_Y(y) = \Pr(Y \leq y) = F_{X,Y}(\infty, y) = \int_{-\infty}^y \int_{-\infty}^{\infty} f_{X,Y}(x, v) \, dx \, dv$$

- The marginal density functions of X and Y are:

$$f_X(x) = \int_{-\infty}^{\infty} f_{X,Y}(x, y) \, dy \quad \text{and} \quad f_Y(y) = \int_{-\infty}^{\infty} f_{X,Y}(x, y) \, dx$$

Independence

- Random variables X and Y are called **independent** if:

$X \leq x$ and $Y \leq y$ are independent events for all $x, y \in \mathbb{R}$

which is equivalent to

$$F_{X,Y}(x, y) = F_X(x)F_Y(y) \quad \text{for all } x, y \in \mathbb{R}$$

which, for **continuous** random variables X and Y , is equivalent to

$$f_{X,Y}(x, y) = f_X(x)f_Y(y) \quad \text{for all } x, y \in \mathbb{R}$$

- For Borel-measurable $g, h : \mathbb{R} \rightarrow \mathbb{R}$ (which means $g(X), h(Y)$ are random variables),

X and Y are independent $\implies g(X)$ and $h(Y)$ are independent

(because $g(X)$ is Σ -measurable for Σ -measurable X and Borel-measurable g)

Conditional Distribution

- Let X be a continuous random variable. Let A be an event with $\Pr(A) > 0$. The conditional distribution function of X given the occurrence of A is:

$$F_{X|A}(x) = \Pr(X \leq x | A) = \int_{-\infty}^x f_{X|A}(u) du$$

where the density function $f_{X|A}(x) = \frac{dF_{X|A}(x)}{dx}$

- Law of total probability:** For partition B_1, \dots, B_n of Ω with $\Pr(B_i) > 0$ for all i ,

$$f_X(x) = \sum_{i=1}^n \Pr(B_i) f_{X|B_i}(x)$$

Proof: By taking derivative w.r.t. x on both sides of $\Pr(X \leq x) = \sum_{i=1}^n \Pr(B_i) \Pr(X \leq x | B_i)$

Conditional Distribution

- For (jointly) continuous random variables X and Y , the conditional distribution function of X given $Y = y$ is the function $F_{X|Y}(\cdot | y)$ given by

$$F_{X|Y}(x | y) = \Pr(X \leq x | Y = y) = \int_{-\infty}^x \frac{f_{X,Y}(u, y)}{f_Y(y)} du$$

- This definition makes sense because:

$$\begin{aligned} \Pr(X \leq x | y \leq Y \leq y + dy) &= \frac{\Pr((X \leq x) \cap (y \leq Y \leq y + dy))}{\Pr(y \leq Y \leq y + dy)} \\ &= \frac{\int_{u=-\infty}^x f_{X,Y}(u, y) dy du}{f_Y(y) dy} = \int_{u=-\infty}^x \frac{f_{X,Y}(u, y)}{f_Y(y)} du \end{aligned}$$

Conditional Distribution

- For (jointly) continuous random variables X and Y , the conditional distribution function of X given $Y = y$ is the function $F_{X|Y}(\cdot | y)$ given by

$$F_{X|Y}(x | y) = \Pr(X \leq x | Y = y) = \int_{-\infty}^x \frac{f_{X,Y}(u, y)}{f_Y(y)} du$$

- The conditional density function of $F_{X|Y}$ is given by

$$f_{X|Y}(x | y) = \frac{f_{X,Y}(x, y)}{f_Y(y)} \text{ for any } y \text{ such that } f_Y(y) > 0$$

Conditional Distribution

- For (jointly) continuous random variables X and Y , the conditional distribution function of X given $Y = y$ is the function $F_{X|Y}(\cdot | y)$ given by

$$F_{X|Y}(x | y) = \Pr(X \leq x | Y = y) = \int_{-\infty}^x \frac{f_{X,Y}(u, y)}{f_Y(y)} du$$

- **Law of total probability:** Let $B \subseteq \mathbb{R}$ be an event (a Borel set). For jointly continuous X and Y where Y has **positive density** over $\Omega_Y \subseteq \mathbb{R}$

$$\Pr(X \in B) = \int_{\Omega_Y} \Pr(X \in B | Y = y) \cdot f_Y(y) dy = \int_{\Omega_Y} f_Y(y) \int_B \frac{f_{X,Y}(x, y)}{f_Y(y)} dx dy$$

Expectation

- The expectation (or mean) of a continuous random variable X with pdf f_X (and CDF F_X) is given by

$$\mathbb{E}[X] = \int_{-\infty}^{\infty} x f_X(x) dx = \int_{-\infty}^{\infty} x dF_X(x)$$

- The k th moment of X is accordingly defined by

$$\mathbb{E}[X^k] = \int_{-\infty}^{\infty} x^k f_X(x) dx = \int_{-\infty}^{\infty} x^k dF_X(x)$$

- These quantities are well-defined when the integrals exist.

Double Counting

- If continuous random variable X takes on only nonnegative values (i.e. the density value $f_X(x) = 0$ if $x < 0$)

$$\mathbb{E}[X] = \int_0^{\infty} [1 - F_X(x)] dx = \int_0^{\infty} \Pr(X > x) dx$$

- **Proof:**

$$\begin{aligned} \int_0^{\infty} [1 - F_X(x)] dx &= \int_0^{\infty} \Pr(X > x) dx = \int_0^{\infty} \left(\int_x^{\infty} f_X(u) du \right) dx \\ &= \int_{u=0}^{\infty} f_X(u) \int_{x=0}^u 1 dx du = \int_0^{\infty} u f_X(u) du = \mathbb{E}[X] \end{aligned}$$

Change of Variables, *LOTUS*

- If X is a continuous random variable and $g(X)$ is a random variable, then

$$\mathbb{E}[g(X)] = \int_{-\infty}^{\infty} g(x)f_X(x) dx$$

- **Proof:** First, assume $g \geq 0$. Denote $B_y = \{x \mid g(x) > y\}$.

$$\mathbb{E}[g(X)] = \int_0^{\infty} \Pr(g(X) > y) dy = \int_0^{\infty} \int_{B_y} f_X(x) dx dy = \int_{-\infty}^{\infty} f_X(x) \int_0^{g(x)} 1 dy dx = \int_{-\infty}^{\infty} g(x)f_X(x) dx$$

For general $g : \mathbb{R} \rightarrow \mathbb{R}$, write $g = g^+ - g^-$ for $g^+, g^- \geq 0$. Then

$$\mathbb{E}[g(X)] = \mathbb{E}[g^+(X)] - \mathbb{E}[g^-(X)] = \int_{-\infty}^{\infty} g^+(x)f_X(x) dx - \int_{-\infty}^{\infty} g^-(x)f_X(x) dx = \int_{-\infty}^{\infty} g(x)f_X(x) dx$$

Linearity of Expectation

- For $a, b \in \mathbb{R}$ and random variables X and Y :
 - $\mathbb{E}[aX + b] = a\mathbb{E}[X] + b$
 - $\mathbb{E}[X + Y] = \mathbb{E}[X] + \mathbb{E}[Y]$

Proof: $\mathbb{E}[aX + b] = \int_{-\infty}^{\infty} (ax + b)f_X(x) dx = a \int_{-\infty}^{\infty} xf_X(x) dx + b \int_{-\infty}^{\infty} f_X(x) dx = a\mathbb{E}[X] + b$

$$\begin{aligned}\mathbb{E}[X + Y] &= \iint_{\mathbb{R}^2} (x + y)f_{(X,Y)}(x, y) dx dy = \iint_{\mathbb{R}^2} xf_{(X,Y)}(x, y) dx dy + \iint_{\mathbb{R}^2} yf_{(X,Y)}(x, y) dx dy \\ &= \int_{-\infty}^{\infty} xf_{(X)}(x) dx + \int_{-\infty}^{\infty} yf_{(Y)}(y) dy = \mathbb{E}[X] + \mathbb{E}[Y]\end{aligned}$$

Monotonicity of Expectation

- Let X and Y be random variables.
 - If $X \geq 0$, then $\mathbb{E}[X] \geq 0$
 - If $X \geq Y$, then $\mathbb{E}[X] \geq \mathbb{E}[Y]$

Proof: If $X \geq 0$, then $\mathbb{E}[X] = \int_0^{\infty} [1 - F_X(x)] dx$ is clearly nonnegative

If $X \geq Y$, then let $Z = X - Y \geq 0$, then by linearity of expectation

$$0 \leq \mathbb{E}[Z] = \mathbb{E}[X] - \mathbb{E}[Y] \implies \mathbb{E}[X] \geq \mathbb{E}[Y]$$

Total Expectation

- Let events B_1, B_2, \dots, B_n be a partition of Ω such that $\Pr(B_i) > 0$ for all i .

$$\mathbb{E}[X] = \sum_{i=1}^n \mathbb{E}[X | B_i] \Pr(B_i)$$

- $\mathbb{E}[\mathbb{E}[X | Y]] = \mathbb{E}[X]$, thus $\Pr(B) = \int_{-\infty}^{\infty} \Pr(B | X = x) f_X(x) dx$ by $\mathbb{E}[\mathbb{E}[I_B | X]]$

Proof:
$$\mathbb{E}[X] = \int_{-\infty}^{\infty} x f_X(x) dx = \int_{-\infty}^{\infty} x \sum_{i=1}^n \Pr(B_i) f_{X|B_i}(x) dx = \sum_{i=1}^n \mathbb{E}[X | B_i] \Pr(B_i)$$

$$\mathbb{E}[\mathbb{E}[X | Y]] = \int_{-\infty}^{\infty} \mathbb{E}[X | Y = y] f_Y(y) dy = \int_{-\infty}^{\infty} f_Y(y) \int_{-\infty}^{\infty} x \frac{f_{X,Y}(x, y)}{f_Y(y)} dx dy = \int_{-\infty}^{\infty} x f_X(x) dx = \mathbb{E}[X]$$

Expectation of Product

- If random variables X and Y are independent, then

$$\mathbb{E}[XY] = \mathbb{E}[X]\mathbb{E}[Y]$$

and hence $\mathbf{Cov}(X, Y) = \mathbb{E}[XY] - \mathbb{E}[X]\mathbb{E}[Y] = 0$

- Consequently, $\mathbf{Var} \left[\sum_{i=1}^n X_i \right] = \sum_{i=1}^n \mathbf{Var}[X_i]$ for pairwise independent X_1, \dots, X_n

Proof: By change of variable

$$\begin{aligned} \mathbb{E}[XY] &= \iint_{\mathbb{R}^2} xy f_{X,Y}(x, y) \, dx \, dy = \iint_{\mathbb{R}^2} xy f_X(x) f_Y(y) \, dx \, dy \\ &= \int_{-\infty}^{\infty} x f_X(x) \, dx \int_{-\infty}^{\infty} y f_Y(y) \, dy = \mathbb{E}[X]\mathbb{E}[Y] \end{aligned}$$

Continuous Probability Distributions

Continuous Uniform Distribution

- The random variable X is **uniform** on $[a, b]$ (or $[a, b)$, $(a, b]$, (a, b)), if it has

$$\text{pdf } f(x) = \begin{cases} \frac{1}{b-a} & \text{if } a < x < b \\ 0 & \text{otherwise} \end{cases} \quad \text{and} \quad \text{CDF } F(x) = \begin{cases} 0 & \text{if } x \leq a \\ \frac{x-a}{b-a} & \text{if } a < x \leq b \\ 1 & \text{if } x > b \end{cases}$$

- There is no uniform distribution on $[a, \infty)$, or on $(-\infty, b]$, or on \mathbb{R}

Continuous Uniform Distribution

- The random variable X is **uniform** on $[a, b]$ (or $[a, b)$, $(a, b]$, (a, b)), if it has

$$\text{pdf } f(x) = \begin{cases} \frac{1}{b-a} & \text{if } a < x < b \\ 0 & \text{otherwise} \end{cases} \quad \text{and} \quad \text{CDF } F(x) = \begin{cases} 0 & \text{if } x \leq a \\ \frac{x-a}{b-a} & \text{if } a < x \leq b \\ 1 & \text{if } x > b \end{cases}$$

- $\mathbb{E}[X] = \int_a^b \frac{x}{b-a} dx = \frac{a+b}{2}$ (same as the discrete uniform distribution on $[a, b]$)

- $\mathbb{E}[X^2] = \int_a^b \frac{x^2}{b-a} dx = \frac{a^2 + b^2 + ab}{3} \implies \mathbf{Var}[X] = \mathbb{E}[X^2] - \mathbb{E}[X]^2 = \frac{(b-a)^2}{12}$

(different from the discrete uniform distribution on $[a, b]$)

Rejection Sampling

- Let X be a uniform random variable on $[a, b]$. Then for any $[c, d] \subseteq [a, b]$,

$$\Pr(X \in [c, d]) = \frac{d - c}{b - a}$$

and given that $X \in [c, d]$, the **conditional distribution** of X is uniform on $[c, d]$:

$$\Pr(X \leq x \mid X \in [c, d]) = \begin{cases} 0 & \text{if } x \leq c \\ \frac{x - c}{d - c} & \text{if } c < x \leq d \\ 1 & \text{if } x > d \end{cases}$$

- **Proof:**
$$\Pr(X \leq x \mid X \in [c, d]) = \frac{\Pr(X \in [a, x] \cap [c, d])}{\Pr(X \in [c, d])}$$

Simulation of General Distribution (Inverse transform sampling)

- Let random variable U be uniform on $[0,1]$. Let $F : \mathbb{R} \rightarrow [0,1]$ be a CDF.
 - If F is continuous, then the random variable $X = F^{-1}(U)$ has CDF F .
 - If F is the CDF of a integer-valued discrete random variable, then the discrete random variable $X = k$ iff $F(k - 1) < U \leq F(k)$ has CDF F .
- **Idea:** The inverse function F^{-1} gives the quantile of the random variable X .

$$\text{Proof: } \Pr(X \leq x) = \Pr(F^{-1}(U) \leq x) = \Pr(U \leq F(x)) = \frac{F(x) - 0}{1 - 0} = F(x)$$

$$\Pr(X = k) = \Pr(F(k - 1) < U \leq F(k)) = F(k) - F(k - 1)$$

Stochastic Domination and Coupling

- If random variables X and Y satisfy $F_X(u) \leq F_Y(u)$ for all $u \in \mathbb{R}$, then we say that X dominates Y stochastically, and write $X \succeq_{\text{st}} Y$
- $X \succeq_{\text{st}} Y$ iff there is a coupling (X', Y') of X and Y with marginal distributions $F_{X'} = F_X$ and $F_{Y'} = F_Y$ respectively, such that $\Pr(X' \geq Y') = 1$

Proof: Let random variable U be uniform on $[0,1]$.

Let $X' = F_X^{-1}(U)$ and $Y' = F_Y^{-1}(U)$ (or if X, Y are discrete, $X' = k$ iff $F_X(k-1) < U \leq F_X(k)$,
 $Y' = k$ iff $F_Y(k-1) < U \leq F_Y(k)$).

By inverse transform sampling, marginal distributions $F_{X'} = F_X$ and $F_{Y'} = F_Y$

And $X' = F_X^{-1}(U) \geq F_Y^{-1}(U) = Y'$ since $F_X(u) \leq F_Y(u)$ for all $u \in \mathbb{R}$

Exponential Distribution

- The random variable X is **exponential** with parameter $\lambda > 0$, if it has

$$\text{pdf } f(x) = \lambda e^{-\lambda x} \quad \text{and} \quad \text{CDF } F(x) = 1 - e^{-\lambda x}, \quad \text{for } x \geq 0$$

- Continuous limit of geometric distribution:** an i.i.d. Bernoulli trial (with $p = \lambda\delta$) being performed after every δ time elapse, let X be the time of the first success

$$\Pr(X > x) = (1 - p)^{x/\delta} = (1 - \lambda\delta)^{x/\delta} \rightarrow e^{-\lambda x} \quad \text{as } \delta \downarrow 0$$

Exponential Distribution

- The random variable X is **exponential** with parameter $\lambda > 0$, if it has

$$\text{pdf } f(x) = \lambda e^{-\lambda x} \quad \text{and} \quad \text{CDF } F(x) = 1 - e^{-\lambda x}, \quad \text{for } x \geq 0$$

- $$\mathbb{E}[X] = \int_0^{\infty} x \lambda e^{-\lambda x} dx = - \int_0^{\infty} x de^{-\lambda x} = (-xe^{-\lambda x}) \Big|_0^{\infty} + \int_0^{\infty} e^{-\lambda x} dx = \frac{1}{\lambda}$$

- alternatively,
$$\mathbb{E}[X] = \int_0^{\infty} (1 - F(x)) dx = \int_0^{\infty} e^{-\lambda x} dx = \frac{1}{\lambda}$$

- $$\mathbb{E}[X^2] = \int_0^{\infty} x^2 \lambda e^{-\lambda x} dx = \frac{2}{\lambda^2} \implies \mathbf{Var}[X] = \mathbb{E}[X^2] - \mathbb{E}[X]^2 = \frac{1}{\lambda^2}$$

Exponential Distribution

- Exponential random variable X is memoryless: for $s, t \geq 0$

$$\Pr(X > s + t \mid X > t) = \Pr(X > s)$$

It's the only memoryless continuous random variable

Proof: $\Pr(X > s + t \mid X > t) = \frac{\Pr(X > s + t)}{\Pr(X > t)} = \frac{e^{-\lambda(s+t)}}{e^{-\lambda t}} = e^{-\lambda s} = \Pr(X > s)$

- If X_1, \dots, X_n are independent exponential random variables with parameters $\lambda_1, \dots, \lambda_n$, respectively, then $\min_{1 \leq i \leq n} X_i$ is exponential with parameter $\sum_{i=1}^n \lambda_i$.

Proof: $\Pr\left(\min_{1 \leq i \leq n} X_i > x\right) = \Pr\left(\bigcap_{1 \leq i \leq n} (X_i > x)\right) = \prod_{i=1}^n \Pr(X_i > x) = \prod_{i=1}^n e^{-x\lambda_i} = e^{-x \sum_{i=1}^n \lambda_i}$

"Poisson"
clock

Poisson Point Process

(Stochastic counting process with exponential interarrival)

- The Poisson process $\{N(t) \mid t \geq 0\}$ with rate $\lambda > 0$ is a continuous time process defined as follows — — imagine we have such a clock:
 - $N(t)$ counts the number of times the clock rings up to time t , initially $N(0) = 0$;
 - The time elapse (interarrival time) between any two consecutive ringings (including the time elapse before 1st ringing) is independent exponential with parameter λ
- Due to memoryless and minimum: The process defined by k independent clocks with the same rate λ is equivalent to the 1-clock process with rate $k\lambda$
- (**Poisson distribution**) For any $t, s \geq 0$ and any integer $n \geq 0$,

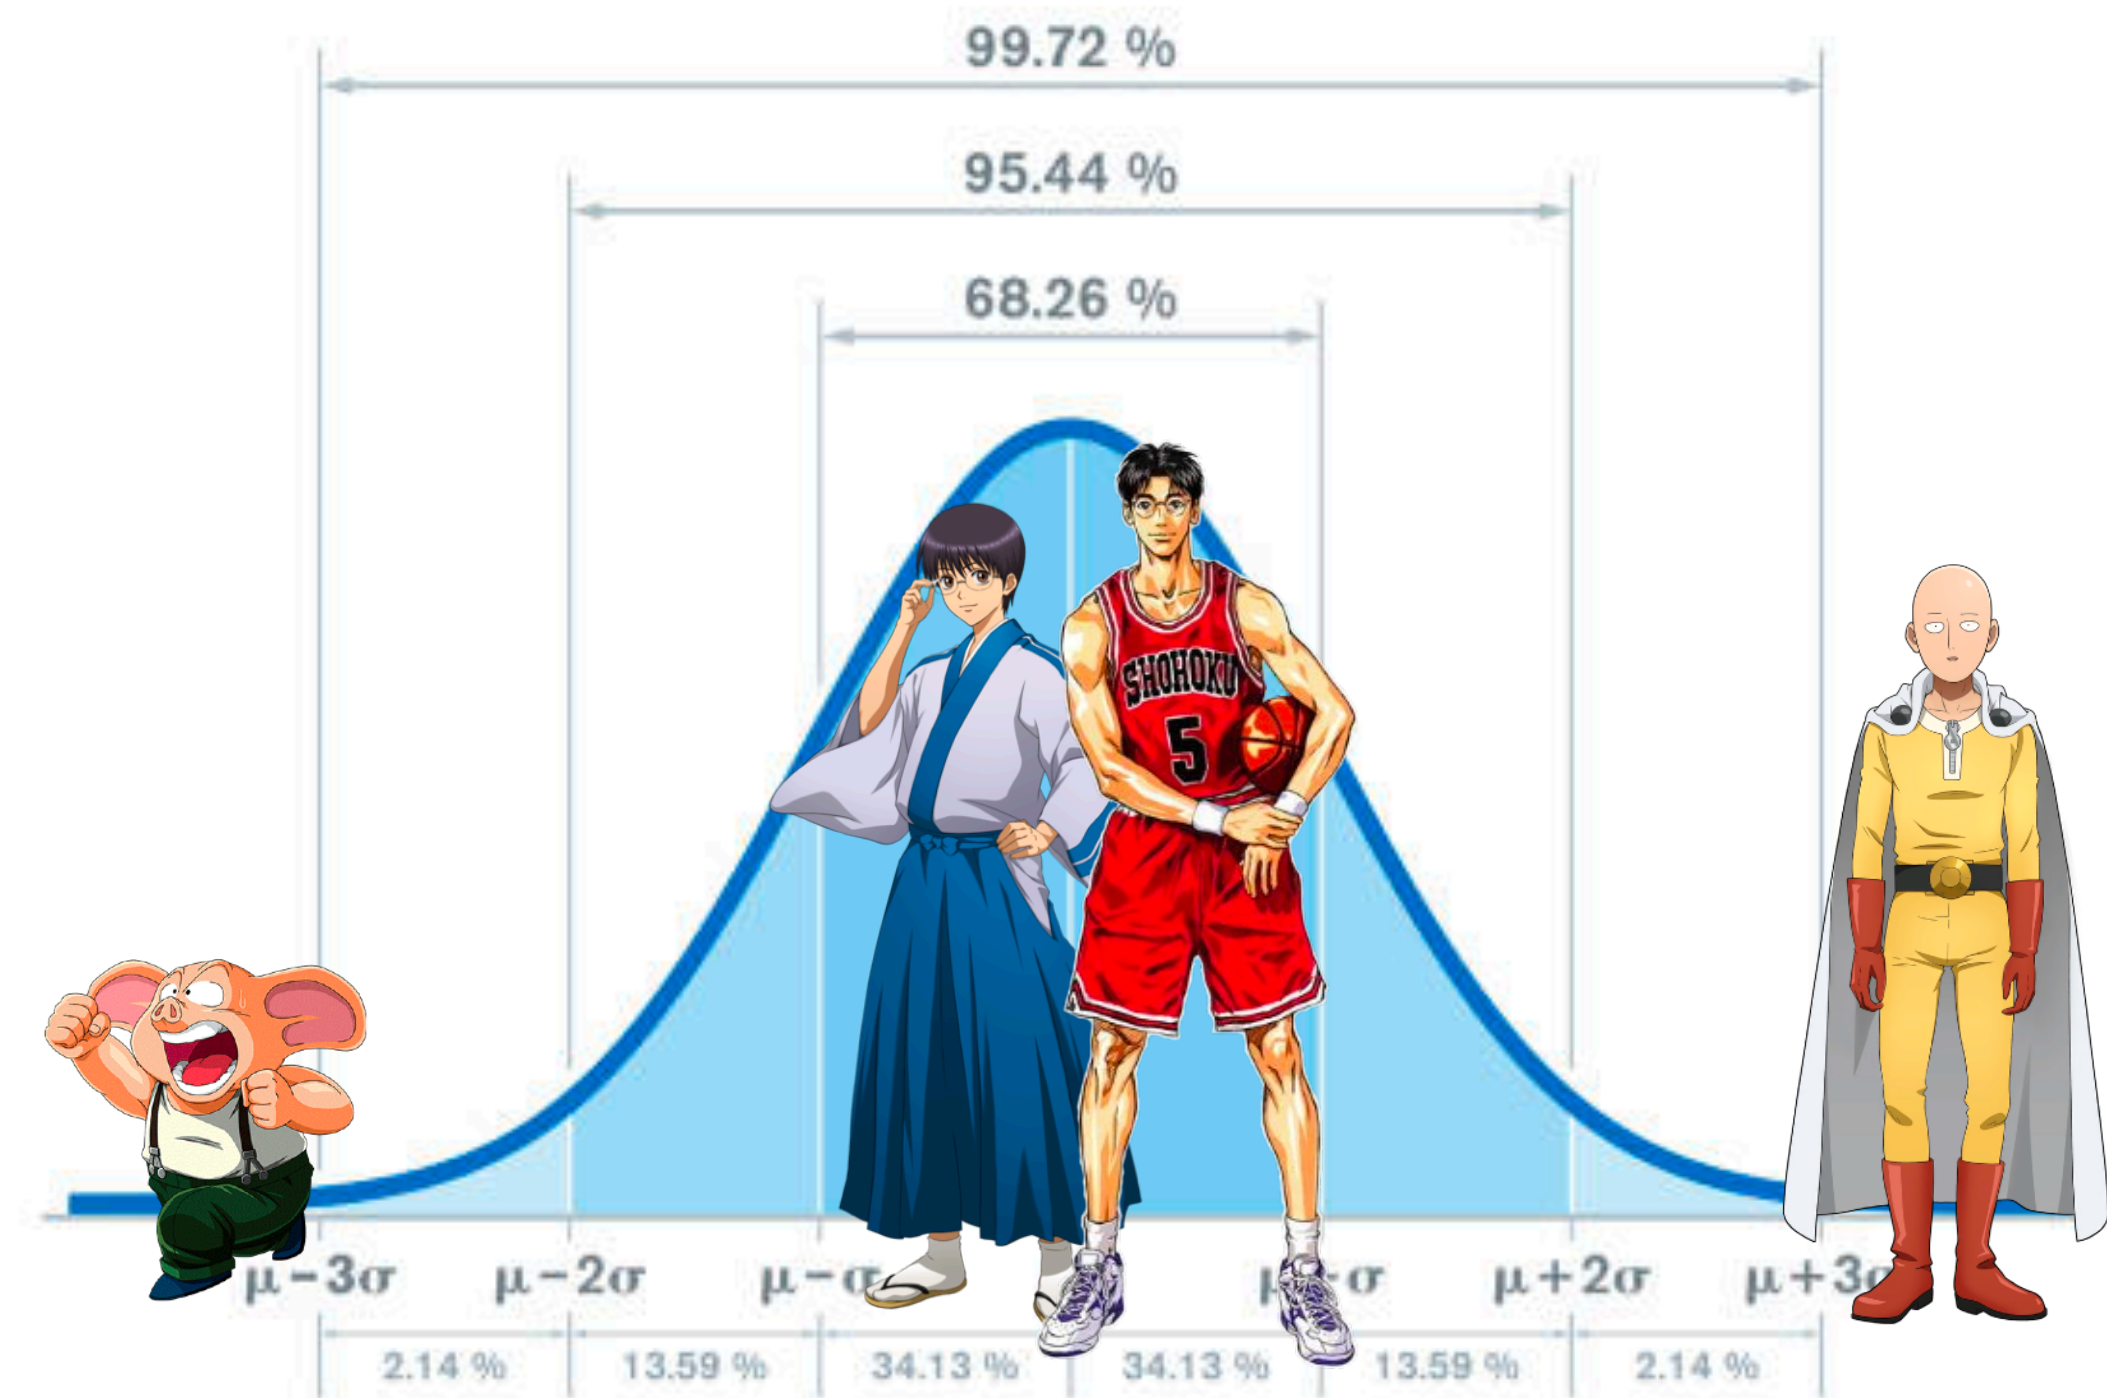

$$\Pr(N(t + s) - N(s) = n) = e^{-\lambda t} \frac{(\lambda t)^n}{n!}$$

Gaussian Distribution

*Ich bin
normal*
(I'm normal)

Normal Distribution

Generating a Uniform Unit Vector

- **Goal:** Draw a uniform random unit vector $U \in \mathbb{R}^n$ with $\|U\|_2 = 1$
- A standard approach is to draw *i.i.d.* $X_1, \dots, X_n \in \mathbb{R}$ and then normalize:

$$U = \frac{(X_1, \dots, X_n)}{\|(X_1, \dots, X_n)\|_2} \text{ so that } \|U\|_2 = 1$$

- Such U is uniform on the **unit sphere**, if the joint density of (X_1, \dots, X_n) is **spherically symmetric**:

$$f_{(X_1, \dots, X_n)}(x_1, \dots, x_n) = \prod_{i=1}^n f_{X_i}(x_i) = \prod_{i=1}^n f_{X_i}(y_i) = f_{(X_1, \dots, X_n)}(y_1, \dots, y_n), \text{ given } \|x\|_2 = \|y\|_2$$

- This suggests random variable with density $f(x) \propto \exp(-c \cdot x^2)$

Normal Distribution (正态分布) (the most important continuous distribution)

- A continuous random variable X is a **normal** or **Gaussian** random variable with parameters $\mu \in \mathbb{R}$ and $\sigma > 0$, if it has the density function:

$$f_X(x) = \frac{1}{\sqrt{2\pi}\sigma} \exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right), \quad -\infty < x < \infty$$

- The distribution is denoted by $N(\mu, \sigma^2)$. If $\mu = 0$ and $\sigma = 1$, then

$$f_X(x) = \frac{1}{\sqrt{2\pi}} e^{-x^2/2}, \quad -\infty < x < \infty$$

is the density of the **standard normal distribution** (标准正态分布) $N(0,1)$

Normal Distribution (正态分布) (the most important continuous distribution)

- It defines a probability distribution because the **Gaussian integral**

$$\int_{-\infty}^{\infty} e^{-x^2} dx = \sqrt{\pi}$$

- The normal distribution is important because it naturally arises in many ways:
 - (*de Moivre–Laplace theorem*) The normal distribution is a continuous limit of the binomial distribution $B(n, p)$ as $n \rightarrow \infty$
 - (*central limit theorem, CLT*) The sum of large number of independent random variables is approximately normally distributed.

Normal Distribution (正态分布)

- If X is a normal random variable with parameters $\mu \in \mathbb{R}$ and $\sigma > 0$, then

$$\mathbb{E}[X] = \mu \quad \text{and} \quad \mathbf{Var}[X] = \sigma^2$$

Proof: $\mathbb{E}[X] = \mu$ because the density $f_X(x) = \frac{1}{\sqrt{2\pi}\sigma} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$ is symmetric w.r.t. $x = \mu$

$$\begin{aligned} \mathbf{Var}[X] &= \frac{1}{\sqrt{2\pi}\sigma} \int_{-\infty}^{\infty} (x - \mu)^2 e^{-\frac{(x-\mu)^2}{2\sigma^2}} dx = \frac{\sigma^2}{\sqrt{2\pi}} \int_{-\infty}^{\infty} y^2 e^{-y^2/2} dy \\ &= \frac{\sigma^2}{\sqrt{2\pi}} \left(-ye^{-y^2/2} \right) \Big|_{-\infty}^{\infty} + \sigma^2 \int_{-\infty}^{\infty} \frac{1}{\sqrt{2\pi}} e^{-y^2/2} dy = \sigma^2 \end{aligned}$$

Linear Transformation of Normal Distribution

- If $X \sim N(\mu, \sigma^2)$, then for any constants $a \neq 0$ and b , the random variable

$$Y = aX + b \sim N(a\mu + b, a^2\sigma^2)$$

Proof: Suppose $a > 0$. $F_Y(y) = \Pr(Y \leq y) = \Pr(X \leq (y - b)/a) = F_X\left(\frac{y - b}{a}\right)$

By chain rule for derivative: $f_Y(y) = \frac{dF_Y(y)}{dy} = \frac{1}{a} f_X\left(\frac{y - b}{a}\right)$

Suppose $a < 0$. $F_Y(y) = 1 - F_X\left(\frac{y - b}{a}\right)$ and $f_Y(y) = \frac{1}{-a} f_X\left(\frac{y - b}{a}\right)$

Thus, $f_Y(y) = \frac{1}{|a|} f_X\left(\frac{y - b}{a}\right) = \frac{1}{\sqrt{2\pi} |a| \sigma} e^{-\frac{(y - a\mu - b)^2}{2a^2\sigma^2}}$

Linear Transformation of Normal Distribution

- If $X \sim N(\mu, \sigma^2)$, then for any constants $a \neq 0$ and b , the random variable

$$Y = aX + b \sim N(a\mu + b, a^2\sigma^2)$$

- If $X \sim N(\mu, \sigma^2)$, then $\frac{X - \mu}{\sigma} \sim N(0, 1)$
- If $X \sim N(0, 1)$, then $\sigma X + \mu \sim N(\mu, \sigma)$

Linear Transformation of Normal Distribution

- If $X \sim N(\mu, \sigma^2)$ and $Y \sim N(\nu, \tau^2)$ are independent, then

$$X + Y \sim N(\mu + \nu, \sigma^2 + \tau^2)$$

Convolution (卷积)

- The convolution of density functions f_X and f_Y is a function $f_X * f_Y$ given by

$$f_X * f_Y(z) = \int_{-\infty}^{\infty} f_X(x)f_Y(z-x) dx = \int_{-\infty}^{\infty} f_X(z-y)f_Y(y) dy$$

- If continuous random variables X and Y are independent, then

$$f_{X+Y} = f_X * f_Y$$

• **Proof:** $\Pr(X + Y \leq z) = \iint_{u+v \leq z} f_X(u)f_Y(v) du dv = \int_{u=-\infty}^{\infty} \int_{v=-\infty}^{z-u} f_X(u)f_Y(v) dv du$

$$= \int_{x=-\infty}^{\infty} \int_{y=-\infty}^z f_X(x)f_Y(y-x) dy dx = \int_{y=-\infty}^z \int_{x=-\infty}^{\infty} f_X(x)f_Y(z-x) dx dy$$

Linear Transformation of Normal Distribution

- If $X \sim N(\mu, \sigma^2)$ and $Y \sim N(\nu, \tau^2)$ are independent, then

$$X + Y \sim N(\mu + \nu, \sigma^2 + \tau^2)$$

Proof: By convolution

$$f_{X+Y}(z) = (f_X * f_Y)(z) = \int_{-\infty}^{\infty} f_X(x) f_Y(z - x) dx = \frac{1}{2\pi\sigma\tau} \int_{-\infty}^{\infty} e^{-\frac{(x-\mu)^2}{2\sigma^2} - \frac{(z-x-\nu)^2}{2\tau^2}} dx$$

$$= \frac{1}{\sqrt{2\pi(\sigma^2 + \tau^2)}} e^{-\frac{(z-\mu-\nu)^2}{2(\sigma^2 + \tau^2)}} \int_{-\infty}^{\infty} \frac{1}{\sqrt{2\pi \frac{\sigma^2\tau^2}{\sigma^2 + \tau^2}}} \exp \left[-\frac{\left(x - \frac{\sigma^2(z-\nu) + \tau^2\mu}{\sigma^2 + \tau^2} \right)^2}{2 \cdot \frac{\sigma^2\tau^2}{\sigma^2 + \tau^2}} \right] dx = 1$$

Standard Normal Distribution

- The **PDF** and **CDF** of standard normal random variable $X \sim N(0,1)$ are given respectively by:

- $$\phi(x) = \frac{1}{\sqrt{2\pi}} e^{-x^2/2}$$

- $$\Phi(z) = \Pr(X \leq z) = \int_{-\infty}^z \frac{1}{\sqrt{2\pi}} e^{-x^2/2} dx$$

- The CDF $\Phi(z)$ does not have a closed-form expression, but is usually computed numerically and given by a **standard normal table**

Standard Normal Table

$$\Phi(z) = \int_{-\infty}^z \frac{1}{\sqrt{2\pi}} e^{-x^2/2} dx$$

- $\Phi(-z) = 1 - \Phi(z)$ by symmetry
- For $X \sim N(\mu, \sigma^2)$ and any x :

$$\Pr(X \leq x) = \Phi\left(\frac{x - \mu}{\sigma}\right)$$

Large Deviation (Concentration) Bound

- If $X \sim N(\mu, \sigma^2)$, then for any $a > 0$,

$$\Pr(|X - \mu| \geq a\sigma) \leq 2e^{-a^2/2}$$

- Still numerically weaker than the “68-95-99.7” empirical rule
- Much sharper than the $1/a^2$ bound by Chebyshev inequality
- Proved using the moment generating function

68-95-99.7 rule

Moment Generating Function

- The moment generating function (MGF) of a random variable X is

$$M_X(t) = \mathbb{E}[e^{tX}]$$

- Expand e^{tX} by Maclaurin series: $M_X(t) = \mathbb{E}[e^{tX}] = \sum_{k \geq 0} \frac{t^k \mathbb{E}[X^k]}{k!}$
- In fact, the k th moment is given by $\mathbb{E}[X^k] = M_X^{(k)}(0)$ where $M_X^{(k)}(0)$ is the k th derivative of $M_X(t)$ evaluated at $t = 0$
- If $M_X(t) = M_Y(t)$ for all $t \in [-\delta, \delta]$ for some $\delta > 0$, then X, Y are identically distributed.

MGF of Normal Distribution

- The moment generating function of standard normal $X \sim N(0,1)$ is

$$M_X(t) = \mathbb{E}[e^{tX}] = e^{t^2/2}$$

Proof: $M_X(t) = \mathbb{E}[e^{tX}] = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{tx} e^{-x^2/2} dx = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-x^2/2+tx} dx$

$$= \frac{1}{\sqrt{2\pi}} e^{t^2/2} \int_{-\infty}^{\infty} e^{(x-t)^2/2} dx = e^{t^2/2} \quad (\text{because } \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{(x-t)^2/2} dx = 1)$$

Large Deviation (Concentration) Bound

- If $X \sim N(\mu, \sigma^2)$, then for any $a > 0$,

$$\Pr(|X - \mu| \geq a\sigma) \leq 2e^{-a^2/2}$$

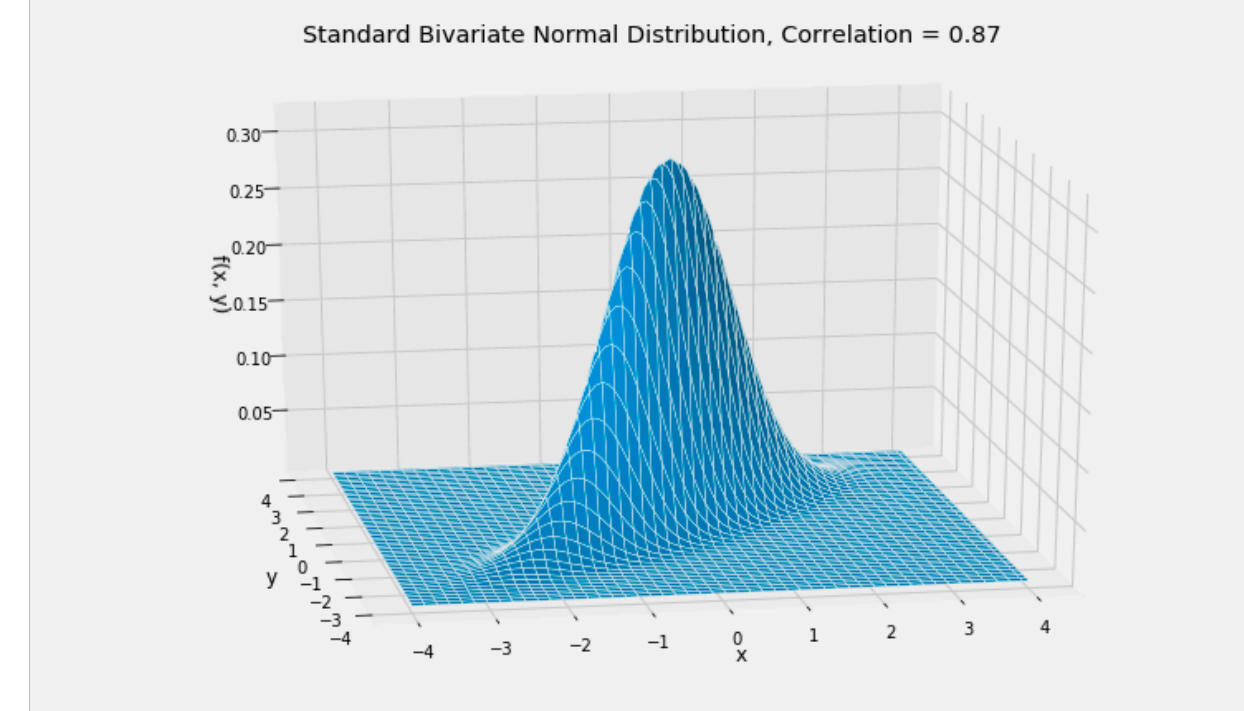

Proof: Consider the standardized $Z = (X - \mu)/\sigma \sim N(0,1)$.

The upper tail: $\Pr(X - \mu \geq a\sigma) = \Pr(Z \geq a) = \Pr(e^{tZ} \geq e^{ta})$ (for any $t > 0$)

$$\begin{aligned} \text{(Markov inequality)} &\leq \mathbb{E}[e^{tZ}] / e^{ta} = e^{t^2/2 - ta} \\ &\leq e^{-a^2/2} \quad \text{(choosing } t = a \text{ that minimizes } e^{t^2/2 - ta}) \end{aligned}$$

The lower tail: $\Pr(X - \mu \leq -a\sigma) = \Pr(Z \leq -a)$ is symmetric.

Bivariate Normal Distribution

- The joint density of standard bivariate normal random variables (X, Y) with parameter $-1 < \rho < 1$, is given by

$$f_{X,Y}(x, y) = \frac{1}{2\pi\sqrt{1-\rho^2}} \exp\left(-\frac{1}{2(1-\rho^2)}(x^2 - 2\rho xy + y^2)\right)$$

- The marginal distributions of X and Y are $N(0,1)$. And

$$\mathbf{Cov}(X, Y) = \mathbb{E}[XY] - \mathbb{E}[X]\mathbb{E}[Y] = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} xyf_{X,Y}(x, y) dx dy = \rho$$

- $\rho = 0 \implies f_{X,Y}(x, y) = \phi(x)\phi(y)$

standard bivariate normal variables are independent \iff they are uncorrelated

Bivariate Normal Distribution

- The joint density of general bivariate normal random variables (X, Y) with means μ_1, μ_2 , variances σ_1^2, σ_2^2 , and correlation $-1 < \rho < 1$, is given by

$$f_{X,Y}(x, y) = \frac{1}{2\pi\sigma_1\sigma_2\sqrt{1-\rho^2}} e^{-\frac{1}{2}Q(x,y)}$$

$$\begin{aligned} \text{where } Q(x, y) &= \frac{1}{1-\rho^2} \left[\left(\frac{x-\mu_1}{\sigma_1} \right)^2 - 2\rho \left(\frac{x-\mu_1}{\sigma_1} \right) \left(\frac{y-\mu_2}{\sigma_2} \right) + \left(\frac{y-\mu_2}{\sigma_2} \right)^2 \right] \\ &= (x-\mu_1, y-\mu_2) \begin{bmatrix} \sigma_1^2 & \sigma_1\sigma_2\rho \\ \sigma_1\sigma_2\rho & \sigma_2^2 \end{bmatrix}^{-1} (x-\mu_1, y-\mu_2)^T \end{aligned}$$

- Marginally $X \sim N(\mu_1, \sigma_1^2)$, $Y \sim N(\mu_2, \sigma_2^2)$, and $\mathbf{Cov}(X, Y) = \sigma_1\sigma_2\rho$

Multivariate Normal Distribution*

- A random vector $Y = (Y_1, \dots, Y_n)$ has a multivariate normal distribution, iff there is an $A \in \mathbb{R}^{n \times k}$, a vector $X = (X_1, \dots, X_k)$ of k independent standard normal random variables, and a vector $\boldsymbol{\mu} = (\mu_1, \dots, \mu_n) \in \mathbb{R}^n$, such that

$$Y^T = AX^T + \boldsymbol{\mu}^T$$

- If further $\boldsymbol{\Sigma} = AA^T = \mathbb{E}[(Y - \boldsymbol{\mu})(Y - \boldsymbol{\mu})^T]$ has full rank, then the density of Y is

$$f(\mathbf{y}) = f(y_1, \dots, y_n) = \frac{1}{\sqrt{(2\pi)^n \det(\boldsymbol{\Sigma})}} e^{-\frac{1}{2}(\mathbf{y} - \boldsymbol{\mu})\boldsymbol{\Sigma}^{-1}(\mathbf{y} - \boldsymbol{\mu})^T}$$

- Denote $Y \sim N(\boldsymbol{\mu}, \boldsymbol{\Sigma})$. Marginally, each $Y_i \sim N(\mu_i, \Sigma_{ii})$, and $\mathbf{Cov}(Y_i, Y_j) = \Sigma_{ij}$
- Equivalent characterization: $\forall \mathbf{a} \in \mathbb{R}^n$, $\langle \mathbf{a}, Y \rangle = a_1 Y_1 + \dots + a_n Y_n$ is normal

Chi-squared (χ^2) distribution

- If Z_1, \dots, Z_k are independent standard normal random variables, then

$$Q = \sum_{i=1}^k Z_i^2$$

follows the chi-squared (卡方) distribution with k degrees of freedom, denoted as $Q \sim \chi^2(k)$

- $\mathbb{E}[Z_i^2] = \mathbf{Var}[Z_i] = 1$ since $Z_i \sim N(0,1) \implies \mathbb{E}[Q] = k$
- sum of independent $\chi^2(k)$ and $\chi^2(l)$ random variables follows $\chi^2(k + l)$

Chi-squared (χ^2) distribution

- Let $Z \sim N(0,1)$ and $Y = Z^2$. Then for any $y \geq 0$,

$$\begin{aligned} F_Y(y) &= \Pr(Y \leq y) = \Pr(Z^2 \leq y) = \Pr(-\sqrt{y} \leq Z \leq \sqrt{y}) \\ &= \Phi(\sqrt{y}) - \Phi(-\sqrt{y}) = 2\Phi(\sqrt{y}) - 1 \end{aligned}$$

- By chain rule: $f_Y(y) = \frac{dF_Y(y)}{dy} = 2 \frac{d\Phi(\sqrt{y})}{dy} = \frac{1}{\sqrt{y}} \phi(\sqrt{y}) = \frac{1}{\sqrt{2\pi y}} e^{-y/2}$

- $\chi^2(1)$ has pdf $f(x) = \frac{1}{\sqrt{2\pi x}} e^{-x/2}$.

- For general integer $k \geq 1$: $\chi^2(k)$ has pdf $f(x) = \frac{1}{2^{k/2} \Gamma(k/2)} x^{k/2-1} e^{-x/2}$

Other Continuous Probability Distributions

Gamma Function*

- Gamma function $\Gamma(x)$: analytic extension of factorial $\Gamma(n) = (n - 1)!$

$$\Gamma(x) = \int_0^{\infty} t^{x-1} e^{-t} dt, \quad \text{for } x > 0$$

- $\Gamma(1) = \int_0^{\infty} e^{-t} dt = 1$ gives exponential distribution with $\lambda = 1$
- $\Gamma(k) = \int_0^{\infty} (\lambda t)^{k-1} \lambda e^{-\lambda t} dt = \mathbb{E}[(\lambda X)^{k-1}]$ for exponential X with parameter 1

Gamma Distribution*

- The random variable X has the gamma distribution with parameters $k, \lambda > 0$, denoted $\Gamma(k, \lambda)$ or $\text{Gamma}(k, \lambda)$, if it has the density

$$f_X(x) = \frac{1}{\Gamma(k)} (\lambda x)^{k-1} \cdot \lambda e^{-\lambda x}, \quad \text{for } x \geq 0, \quad \text{where } \Gamma(k) = \int_0^{\infty} t^{k-1} e^{-t} dt$$

- $\Gamma(1, \lambda)$ is the exponential distribution with parameter λ
- If $X \sim \Gamma(\alpha, \lambda)$ and $Y \sim \Gamma(\beta, \lambda)$ are independent, then $X + Y \sim \Gamma(\alpha + \beta, \lambda)$
- $\sum_{i=1}^k X_i \sim \Gamma(k, \lambda)$ if X_1, \dots, X_k are i.i.d. exponential random variables with parameter λ
- $\Gamma(k/2, 1/2)$, for integer $k \geq 1$, is the $\chi^2(k)$ distribution

Gamma Distribution*

- The moment generating function of gamma random variable $X \sim \Gamma(k, \lambda)$ is

$$M_X(t) = \mathbb{E}[e^{tX}] = \left(1 - \frac{t}{\lambda}\right)^{-k} \quad \text{for } t < \lambda$$

Proof: $M_X(t) = \mathbb{E}[e^{tX}] = \int_0^{\infty} e^{tx} \cdot f_X(x) dx = \frac{\lambda^k}{\Gamma(k)} \int_0^{\infty} x^{k-1} e^{-(\lambda-t)x} dx$

(substituting $(\lambda - t)x = u$) $= \frac{\lambda^k}{\Gamma(k)(\lambda - t)^k} \int_0^{\infty} u^{k-1} e^{-u} du = \frac{\lambda^k \Gamma(k)}{\Gamma(k)(\lambda - t)^k} = \left(1 - \frac{t}{\lambda}\right)^{-k}$

Gamma Distribution*

- The moment generating function of gamma random variable $X \sim \Gamma(k, \lambda)$ is

$$M_X(t) = \mathbb{E}[e^{tX}] = \left(1 - \frac{t}{\lambda}\right)^{-k} \quad \text{for } t < \lambda$$

- If $X \sim \Gamma(\alpha, \lambda)$ and $Y \sim \Gamma(\beta, \lambda)$ are independent, then for $t < \lambda$

$$M_{X+Y}(t) = \mathbb{E}[e^{t(X+Y)}] = \mathbb{E}[e^{tX} \cdot e^{tY}] = \mathbb{E}[e^{tX}] \cdot \mathbb{E}[e^{tY}] = \left(1 - \frac{t}{\lambda}\right)^{-(\alpha+\beta)}$$

$\implies X + Y \sim \Gamma(\alpha + \beta, \lambda)$ (since MGF uniquely identifies distribution)

Poisson Point Process*

- Let $\{N(t) \mid t \geq 0\}$ be a Poisson process with rate $\lambda > 0$. For any $t, s \geq 0$ and any integer $n \geq 0$,

$$\Pr(N(t + s) - N(s) = n) = e^{-\lambda t} \frac{(\lambda t)^n}{n!}$$

Proof: By memoryless, it suffices to prove $\Pr(N(t) = n) = e^{-\lambda t} \frac{(\lambda t)^n}{n!}$

For i.i.d. exponential random variables X_1, X_2, \dots with parameter λ

$$\begin{aligned} \Pr(N(t) = n) &= \Pr\left(\sum_{i=1}^n X_i \leq t \cap \sum_{i=1}^{n+1} X_i > t\right) = \int_0^t f_{\sum_{i=1}^n X_i}(x) \cdot \Pr(X_{n+1} > t - x) \, dx \\ &= \int_0^t \frac{(\lambda x)^{n-1} \lambda e^{-\lambda x}}{\Gamma(n)} e^{-\lambda(t-x)} \, dx = \frac{\lambda^n e^{-\lambda t}}{\Gamma(n)} \int_0^t x^{n-1} \, dx = \frac{\lambda^n e^{-\lambda t} t^n}{n\Gamma(n)} = e^{-\lambda t} \frac{(\lambda t)^n}{n!} \end{aligned}$$

Beta Distribution*

- The random variable X is beta with parameters $a, b > 0$, if it has the density

$$f_X(x) = \frac{1}{B(a, b)} x^{a-1} (1-x)^{b-1}, \quad \text{for } 0 \leq x \leq 1,$$

where $B(a, b) = \frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)} = \int_0^1 x^{a-1} (1-x)^{b-1} dx$ is the **beta function**

- $\text{Beta}(1,1) \sim$ uniform on $[0,1]$, and $\text{Beta}(1,n) \sim \min_{1 \leq i \leq n} X_i$ for i.i.d. X_i uniform on $[0,1]$
- If $X \sim \Gamma(\alpha, \lambda)$ and $Y \sim \Gamma(\beta, \lambda)$ are independent, then $\frac{X}{X+Y} \sim \text{Beta}(\alpha, \beta)$

Cauchy Distribution*

Bell Curve vs. Cauchy Distribution

- The random variable X has the Cauchy distribution, if it has the density

$$f_X(x) = \frac{1}{\pi(1+x^2)}, \quad -\infty < x < \infty$$

- The Cauchy random variable X **does not have any moment**:

$$\mathbb{E}[X^k] = \infty \text{ for all } k \geq 1$$

- The moment generating function $M_X(t) = \mathbb{E}[e^{tX}]$ does not exist
