Paradigms for Designing Algorithms

Greedy algorithm

- Make a greedy choice
- Prove that the greedy choice is safe
- Reduce the problem to a sub-problem and solve it iteratively
- Usually for optimization problems

Divide-and-conquer

- Break a problem into many **independent** sub-problems
- Solve each sub-problem separately
- Combine solutions for sub-problems to form a solution for the original one
- Usually used to design more efficient algorithms

Paradigms for Designing Algorithms

Dynamic Programming

- Break up a problem into many **overlapping** sub-problems
- Build solutions for larger and larger sub-problems
- Use a **table** to store solutions for sub-problems for reuse

Recall: Computing the n -th Fibonacci Number

- $F_0 = 0, F_1 = 1$
- $F_n = F_{n-1} + F_{n-2}, \forall n \geq 2$
- Fibonacci sequence: 0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, ...

Fib(n)

```
1:  $F[0] \leftarrow 0$ 
2:  $F[1] \leftarrow 1$ 
3: for  $i \leftarrow 2$  to  $n$  do
4:    $F[i] \leftarrow F[i - 1] + F[i - 2]$ 
5: return  $F[n]$ 
```

Avoiding Unnecessary Computation and Memory Using Memoized Algorithm and Hash Map

compute-opt(i, W')

```
1: if  $opt[i, W'] \neq \perp$  then return  $opt[i, W']$ 
2: if  $i = 0$  then  $r \leftarrow 0$ 
3: else
4:    $r \leftarrow \text{compute-opt}(i - 1, W')$ 
5:   if  $w_i \leq W'$  then
6:      $r' \leftarrow \text{compute-opt}(i - 1, W' - w_i) + w_i$ 
7:     if  $r' > r$  then  $r \leftarrow r'$ 
8:    $opt[i, W'] \leftarrow r$ 
9: return  $r$ 
```

- Use hash map for opt

Input: integer bounds $W > 0$, $Z > 0$,

a set of n items, each with an integer weight $w_i > 0$

Edit Distance with Replacing: Reduction to a Variant of LCS

- Need to match letters in A and B , every letter is matched at most once and there should be no crosses.

- Need to maximize the score.
- DP recursion for the case $i > 0$ and $j > 0$:

Matrix Chain Multiplication

Matrix Chain Multiplication

Input: n matrices A_1, A_2, \dots, A_n of sizes

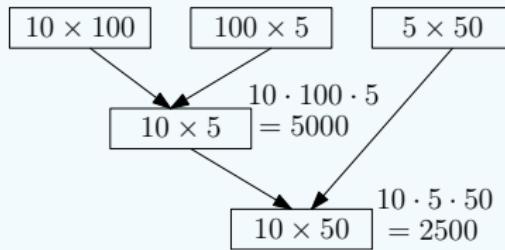

$r_1 \times c_1, r_2 \times c_2, \dots, r_n \times c_n$, such that $c_i = r_{i+1}$ for every $i = 1, 2, \dots, n - 1$.

Output: the order of computing $A_1 A_2 \cdots A_n$ with the minimum number of multiplications

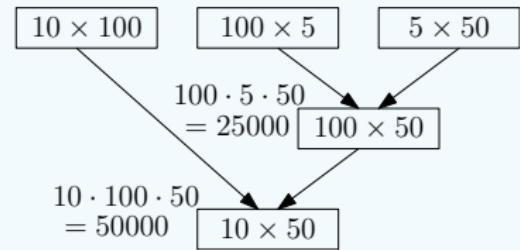

Fact Multiplying two matrices of size $r \times k$ and $k \times c$ takes $r \times k \times c$ multiplications.

Example:

- $A_1 : 10 \times 100, A_2 : 100 \times 5, A_3 : 5 \times 50$

$$\text{cost} = 5000 + 2500 = 7500$$

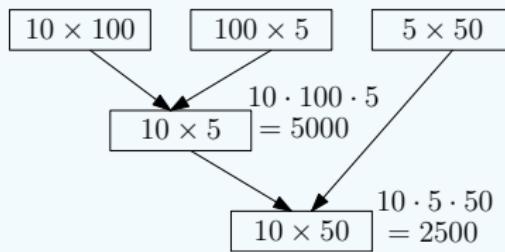

$$\text{cost} = 25000 + 50000 = 75000$$

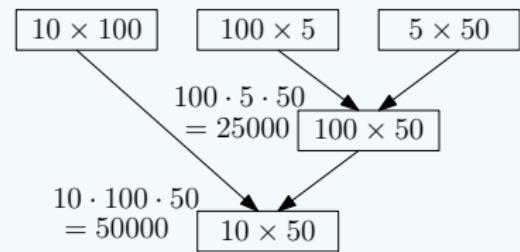

- $(A_1A_2)A_3: 10 \times 100 \times 5 + 10 \times 5 \times 50 = 7500$
- $A_1(A_2A_3): 100 \times 5 \times 50 + 10 \times 100 \times 50 = 75000$

Optimum Binary Search Tree

- n elements $e_1 < e_2 < e_3 < \cdots < e_n$
- e_i has frequency f_i
- goal: build a binary search tree for $\{e_1, e_2, \dots, e_n\}$ with the minimum accessing cost:

Dynamic Programming

- Break up a problem into many **overlapping** sub-problems
- Build solutions for larger and larger sub-problems
- Use a **table** to store solutions for sub-problems for reuse

Comparison with greedy algorithms

- Greedy algorithm: each step is making a small progress towards constructing the solution
- Dynamic programming: the whole solution is constructed in the last step

Comparison with divide and conquer

- Divide and conquer: an instance is broken into many **independent** sub-instances, which are solved separately.
- Dynamic programming: the sub-instances we constructed are overlapping.

Definition of Cells for Problems We Learnt

- Subset sum, knapsack: $opt[i, W'] = \text{value of instance with items } \{1, 2, \dots, i\} \text{ and budget } W'$
- Longest common subsequence: $opt[i, j] = \text{value of instance defined by } A[1..i] \text{ and } B[1..j]$
